注意：解答はすべて別紙解答用紙（5枚の1）～（5枚の5）の指定の欄に記入しなさい。

ディクテーションの解答用紙は（5枚の5）です。

I　次の文章を読んで，下の問いに答えなさい。

A few years ago, I received an e-mail from a man who served in the Rhodesian army in southern Africa in the 1970s, before the end of apartheid. He'd been forced to join the army against his will, handed a uniform and a rifle, and ordered to hunt down guerrilla fighters.

He was deep in the forest one morning, conducting practice exercises with his small squad of soldiers, when he detected movement ahead of him. With a pounding heart, he saw a long line of guerrilla fighters dressed in camouflage and carrying machine guns. Instinctively, he raised his rifle and aimed at the leader, who was carrying a rifle.

Suddenly, he felt a hand on his shoulder. "Don't shoot," whispered his buddy behind him. "It's just a boy." He slowly lowered his rifle, looked again at the scene, and was astonished by what he now saw: a boy, perhaps ten years old, leading a long line of cows. And the rifle? It was a simple guiding stick.

For years afterward, this man struggled to understand (1)the upsetting episode. What was wrong with his brain?

As it turns out, nothing was wrong with his brain. It was working exactly as it should have.

(2)Scientists used to believe that the brain's visual system operated like a camera, detecting the visual information "out there" in the world and constructing a photograph-like image in the mind. Today we know better. Your view of the world is no photograph. It's a construction of your brain that is so fluid and so convincing that it appears to be accurate. But sometimes it's not.

To understand why it can be perfectly normal to see a grown guerrilla fighter with a rifle when you're looking at a ten-year-old boy with a stick, let's consider the situation from the brain's point of view.

From the moment you're born to the moment you draw your last breath, your brain is stuck in a dark, silent box called your skull. Day in and day out, it continually

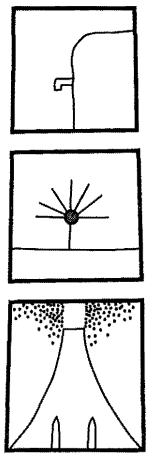
receives sense data from the outside world via your eyes, ears, nose, and other sensory organs. This data does not arrive in the form of the meaningful sights, smells, sounds, and other sensations that most of us experience. It's just a flood of light waves, chemicals, and changes in air pressure with no built-in meaning.

Faced with these ambiguous scraps of sense data, your brain must somehow figure out what to do next. Remember, your brain's most important job is to control your body so you stay alive and well. Your brain must somehow make meaning from the flood of sense data it's receiving so you don't fall down a staircase or become lunch for some wild beast.

How does your brain interpret the sense data so it knows how to proceed? (3) If it used only the ambiguous information that is immediately present, then you'd be swimming in a sea of uncertainty until you figured out the best response. Luckily, your brain has an additional source of information at its disposal: memory. Your brain can draw on your lifetime of past experiences—things that have happened to you personally and things that you've learned about from friends, teachers, books, videos, and other sources. In the blink of an eye, your brain reconstructs bits and pieces of past experience as your neurons pass electrochemical information back and forth in an ever-shifting, complex network. Your brain assembles these bits into memories to infer the meaning of the sense data and guess what to do about it.

Your past experiences include not only what happened in the world around you but also what happened inside your body. Was your heart beating quickly? Were you breathing heavily? Your brain asks itself in every moment, *The last time I encountered a similar situation, when my body was in a similar state, what did I do next?* (4) The answer need not be a perfect match for your situation, just something close enough to give your brain an appropriate plan of action that helps you survive.

Here's a quick demonstration that your memory is a critical ingredient in what you see. Take a look at the following three line drawings.



Inside your skull, without your awareness, billions of your neurons are trying to give these lines and dots meaning. Your brain is searching through a lifetime of past experiences, issuing thousands of guesses at once, weighing probabilities, trying to answer the question *What are these wavelengths of light most like?* And it's all happening faster than you can snap your fingers.

So what do you see? A bunch of black lines and dots? Let's see what happens when your brain receives some more information. Suppose the following explanations were added to these three line drawings: The three figures are a submarine falling down a waterfall, a spider doing a handstand, and a ski jumper looking at spectators far below before pushing off. You should now see familiar objects instead of lines and dots. Your brain is assembling memories from bits and pieces of past experiences to go beyond the visual data in front of you and make meaning. In the process, your brain is literally changing the firing of its own neurons. Objects that you might never have seen before now leap from the page. (5) The lines and dots haven't changed—you have.

do a handstand　逆立ちをする

問１　下線部(1)の内容を，本文に即して具体的に日本語で説明しなさい。

問２　下線部(2)を日本語に直しなさい。

問３　下線部(3)を，文中の it の内容がわかるように，日本語に直しなさい。

問４　下線部(4)を日本語に直しなさい。

問５　下線部(5)の内容を，本文に即して具体例を挙げながら，日本語で説明しなさい。

II　次の文章を読んで，その内容を 250 字程度(句読点等を含む)の日本語で要約しなさい。

Imagine that you all of a sudden found yourself in utter darkness unable to see, in complete silence unable to hear, with your tongue tied unable to speak, and with your senses of taste and smell gone, too. Your only remaining connection to the world is through your sense of touch. Terribly shocking as this may seem for someone who has sampled life for many years through combinations of sights, sounds, flavours and odours, you'd still have the ability to use language. You could at least make yourself understood by writing down what you wanted to say. But imagine that this sensory loss happened before you had developed much command of spoken language, let alone spelling. This was the fate of Laura Bridgman.

Laura was born in 1829. She was a weak child, small and skinny. When she was two, the Bridgmans caught scarlet fever. She survived, but the fever took away her sight, her hearing, and most of her senses of taste and smell. Whatever little language she had learned before the fever soon disappeared, too, and she became mute within a year. Her physical recovery took two years and left her thin and delicate-looking—with her sense of touch as her only connection to the world. Still, she was a spirited child, who used an old boot for a doll and a few simple gestures to communicate with her family.

Dr Samuel Gridley Howe learned of Laura's story and brought her to the Perkins School for the Blind in Boston, where he was the director. At that time, deaf-blind individuals were considered to be simple-minded, regarded as fools, destined for a non-communicative existence in silence and darkness. Howe was eager to showcase the power of the human mind by demonstrating that a deaf-blind child could learn language.

Howe decided to teach Laura English words spelled out using raised letters that could be differentiated by touch. To begin, he would label common objects, such as spoon, book and key, with these letters. Laura soon learned to associate each object with its corresponding letter sequence. Next, Howe gave her each raised letter on a separate piece of paper, arranged next to one another to spell the words she knew: S-P-O-O-N, B-O-O-K, K-E-Y. All the letters were then mixed up in a pile, and Laura was prompted to order them into the labels for the objects she knew. It took a while, but she eventually learned to do this too.

Once Laura had grasped the idea that things have names and that we can use language to talk about them with each other, she was eager to learn words for everything in her world. Howe then introduced her to finger spelling, where the 'speaker' uses the fingers of one hand to form individual letters, and the 'listener' places their hand over the speaker's hand to feel the shape being signalled. Laura quickly mastered finger spelling. She could now 'finger-talk' wherever and whenever she wanted.

Howe described Laura's ever-growing language abilities in the Perkins School annual reports. Her linguistic awakening captured the public's imagination, and she soon became a household name in America. Laura's fame turned international after Charles Dickens met her in 1842 while touring North America and told her story in his travelogue. She remained one of the most famous women in the world for the rest of the 1840s. People in the thousands would attend Perkins exhibition days, where Laura would demonstrate her language skills.

Laura's case is not just a wonderful illustration of the triumph of the human spirit but also a telling example of the spectacular flexibility of our language ability. For starters, she may be the only person whose initial introduction to language was through the printed word. Normally, we only learn to read once we have a decent

mastery of spoken language. For Laura, it was the opposite. Laura's language also had a number of other characteristics. For example, she often invented words. When being taught the meaning of 'alone', she did go to her room and returned alone. Soon thereafter she wanted to go with one of her friends and said 'Laura go **al-two**!'

The fact that Laura was able to create her own unique language—while still being understood by those around her—is evidence to one of the most fundamental properties of human linguistic communication: its immense variety and adaptability.

scarlet fever　猩紅熱（しょうこう）

Ⅲ　次の文章を読んで，下線部(1)～(4)を英語に直しなさい。

世界全体では，人間が食べるために生産された食品の30～40％が実際には食べられていない。(1) スーパーに行き，レジ袋3つ分の食品を買って帰ったとしよう。あなたは自宅に戻って玄関のドアを開ける前に，3つのうち1つの袋をゴミ箱に捨てる。(2) その袋は後日，埋め立て処分場行きだ。なんというムダか。それはまさに，今日私たちが行っていることだ。(3) 毎日8億人を超える人々が飢えていることを考えると，この大量の食品ロスには何ともやりきれない思いがする。(4)
